Experiments on board low-Earth orbit satellites show that energetic electrons and protons (tens of keV) of the Earth's radiation belt can penetrate to the equatorial ionosphere. We present the results of solar-cycle and annual variations of occurrence rate of electrons and protons injections into the ionosphere during the period from 1998 to 2019 years.

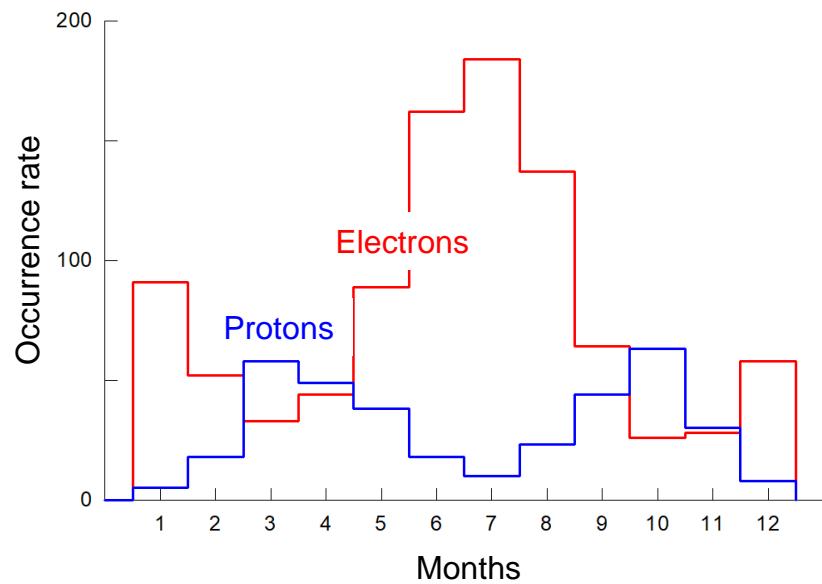

Statistics of particle injections (1998-2019)

Summary

We have found that local ion concentration changed in the regions of penetration of the >30 keV electrons and 30-80 keV protons into the low latitude ionosphere. We showed that increase of ion concentration in the F layer at dawn related with additional ionization of neutral gas by energetic electrons. Ionospheric irregularities at night can be caused by effect of energetic protons.

Thank you for attention !
